

# Non-standard collider signatures

Long-lived particles

Rebeca Gonzalez Suarez - Uppsala University

# How much a particle lives

Depends on many factors

Courtesy of [Patrick Koppenburg](#)

- But the main ones are two:
  - Mass
  - Very massive particles live shortly
- Couplings
  - Strongly coupled particles live shortly

# Take for example

Long-Lived  
Lives literally forever (stable)  
(As far as we know)

?  
2.2 $\mu$ s  
Feels like it could be short-lived

# But what is a long-lived particle?

- We use **Long-lived particles** **as an** umbrella term to cover particles with lifetimes long enough to travel measurable distances inside the detectors before decaying, long enough to have distinct experimental signatures

Long-lived  
 $2.2\mu\text{s}$

Long-Lived  
Stable  
(As far as we know)

And though these two are technically long-lived particles, we tend to use the term to refer to **NEW particles that we have not discovered yet**

# These New, long-lived particles

- are not a prediction of a single new theory, **they fit into virtually all proposed frameworks for BSM physics**
  - Typically Feebly Interacting
- Theoretically, their presence is strongly motivated

Featured in (including but not limited to):

- SUSY
- Compositeness
- Exotic decays (H, Z, hadrons)
- Hidden sectors

# Talking about dark matter and hidden sectors

## Perfect physics cases for long-lived particles!

- We know very little about dark matter, just that it does not interact with regular matter other than gravitationally
  - Dark matter → does not interact a lot → small couplings → long-lived
- Hidden Sectors that could exist in parallel to the standard model
  - Hidden → does not interact a lot → small couplings → long-lived
- In short:
  - **if you are looking for dark matter/hidden sectors, you need to consider long-lived signatures!**

# My favourite long-lived particles

Note: They are all pretty much interconnected

# 1- Heavy Neutral Leptons (HNLs)

## PDG definition

- Dirac or Majorana fermions with sterile neutrino quantum numbers, that are heavy enough to not disrupt the simplest Big Bang Nucleosynthesis bounds and/or unstable on cosmological timescales
- Typically HNLs have mass  $\sim \text{MeV}$  or higher
- Searches for these particles generically set bounds on the mixing between the HNL and the active neutrinos

Current constraints on the electron neutrino-sterile neutrino mixing  $|V_{eN}|^2$  as a function of the sterile neutrino mass  $m_N$  [Ref]

# A BIG question

## Neutrino masses

- Since Neutrino oscillations were discovered, we know that neutrinos have non-zero masses
  - But neutrinos are massless in the SM
- The SM needs to incorporate this experimental fact
  - The simplest way to do this is generating Dirac neutrino masses from the Yukawa couplings through the Higgs mechanism, just like for the other fermions.
  - This requires introducing new “right-handed” neutrinos  $\rightarrow$  new HNL

# The seesaw mechanism

# The matter-antimatter unbalance of the Universe

## Another BIG question

- For the seesaw mechanism to work, if right-handed neutrinos exist, then they would be their own antiparticles.
- If neutrinos are their own antiparticles, it's possible that the antineutrinos emitted during double beta decay could annihilate one another and disappear, violating lepton number conservation via neutrinoless double beta decay.
  - This process would favor matter over antimatter, creating an imbalance
    - That sounds familiar

# Dark matter too!

Conveniently, HNLs also offer a dark matter candidate

| SM       |                              |                             |                              |          |                              | nuMSM                       |                              |          |                              |                             |                              |

Neutrino Portal

- For example: the “νMSM” is the extension of the Minimal SM (SMS) in the neutrino sector, adding three right-handed neutrinos
- can explain simultaneously dark matter, the baryon asymmetry of the Universe, and the neutrino masses and mixings observed experimentally
- The lightest sterile neutrino with mass the keV range → dark matter!

# Complementarity

Spans several fields: Astrophysics/cosmology, accelerators (collider/beam dump), neutrino

Could mean a unified Standard Model of particle physics and cosmology

90% CL exclusion limits for a HNL mixed with the electron neutrino, from the Physics Briefing Book : Input for the European Strategy for Particle Physics Update 2020 (<https://cds.cern.ch/record/2691414/>)

Current and future constraints on the electron neutrino-sterile neutrino mixing  $|V_{eN}|^2$   
as a function of the sterile neutrino mass  $m_N$  [Ref]

# Long-lived Heavy Neutral Leptons

 FUTURE  
CIRCULAR  
COLLIDER

Courtesy of Alain Blondel

- Many of the current limits cover high neutrino mixing values
- For low values of the neutrino mixing angle, the decay length of the heavy neutrino is significant
  - Long-lived signatures
- Flagship of the Future FCC-ee
  - $Z \rightarrow \nu N, N \rightarrow l W$
  - displaced vertex search

# How you generate HNL at colliders?

Via Z or W decay

## 2. ALPs

### Another kind of hidden sector

- You will learn EVERYTHING there is to know about dark sectors this week
- ALPs: axion-like particles. Pseudo-scalar particles predicted by BSM models with a spontaneously broken global symmetry (notably string theory), versatile in terms of mass and SM couplings
  - they could be dark matter candidates in certain regions
  - In others: dark sector mediators

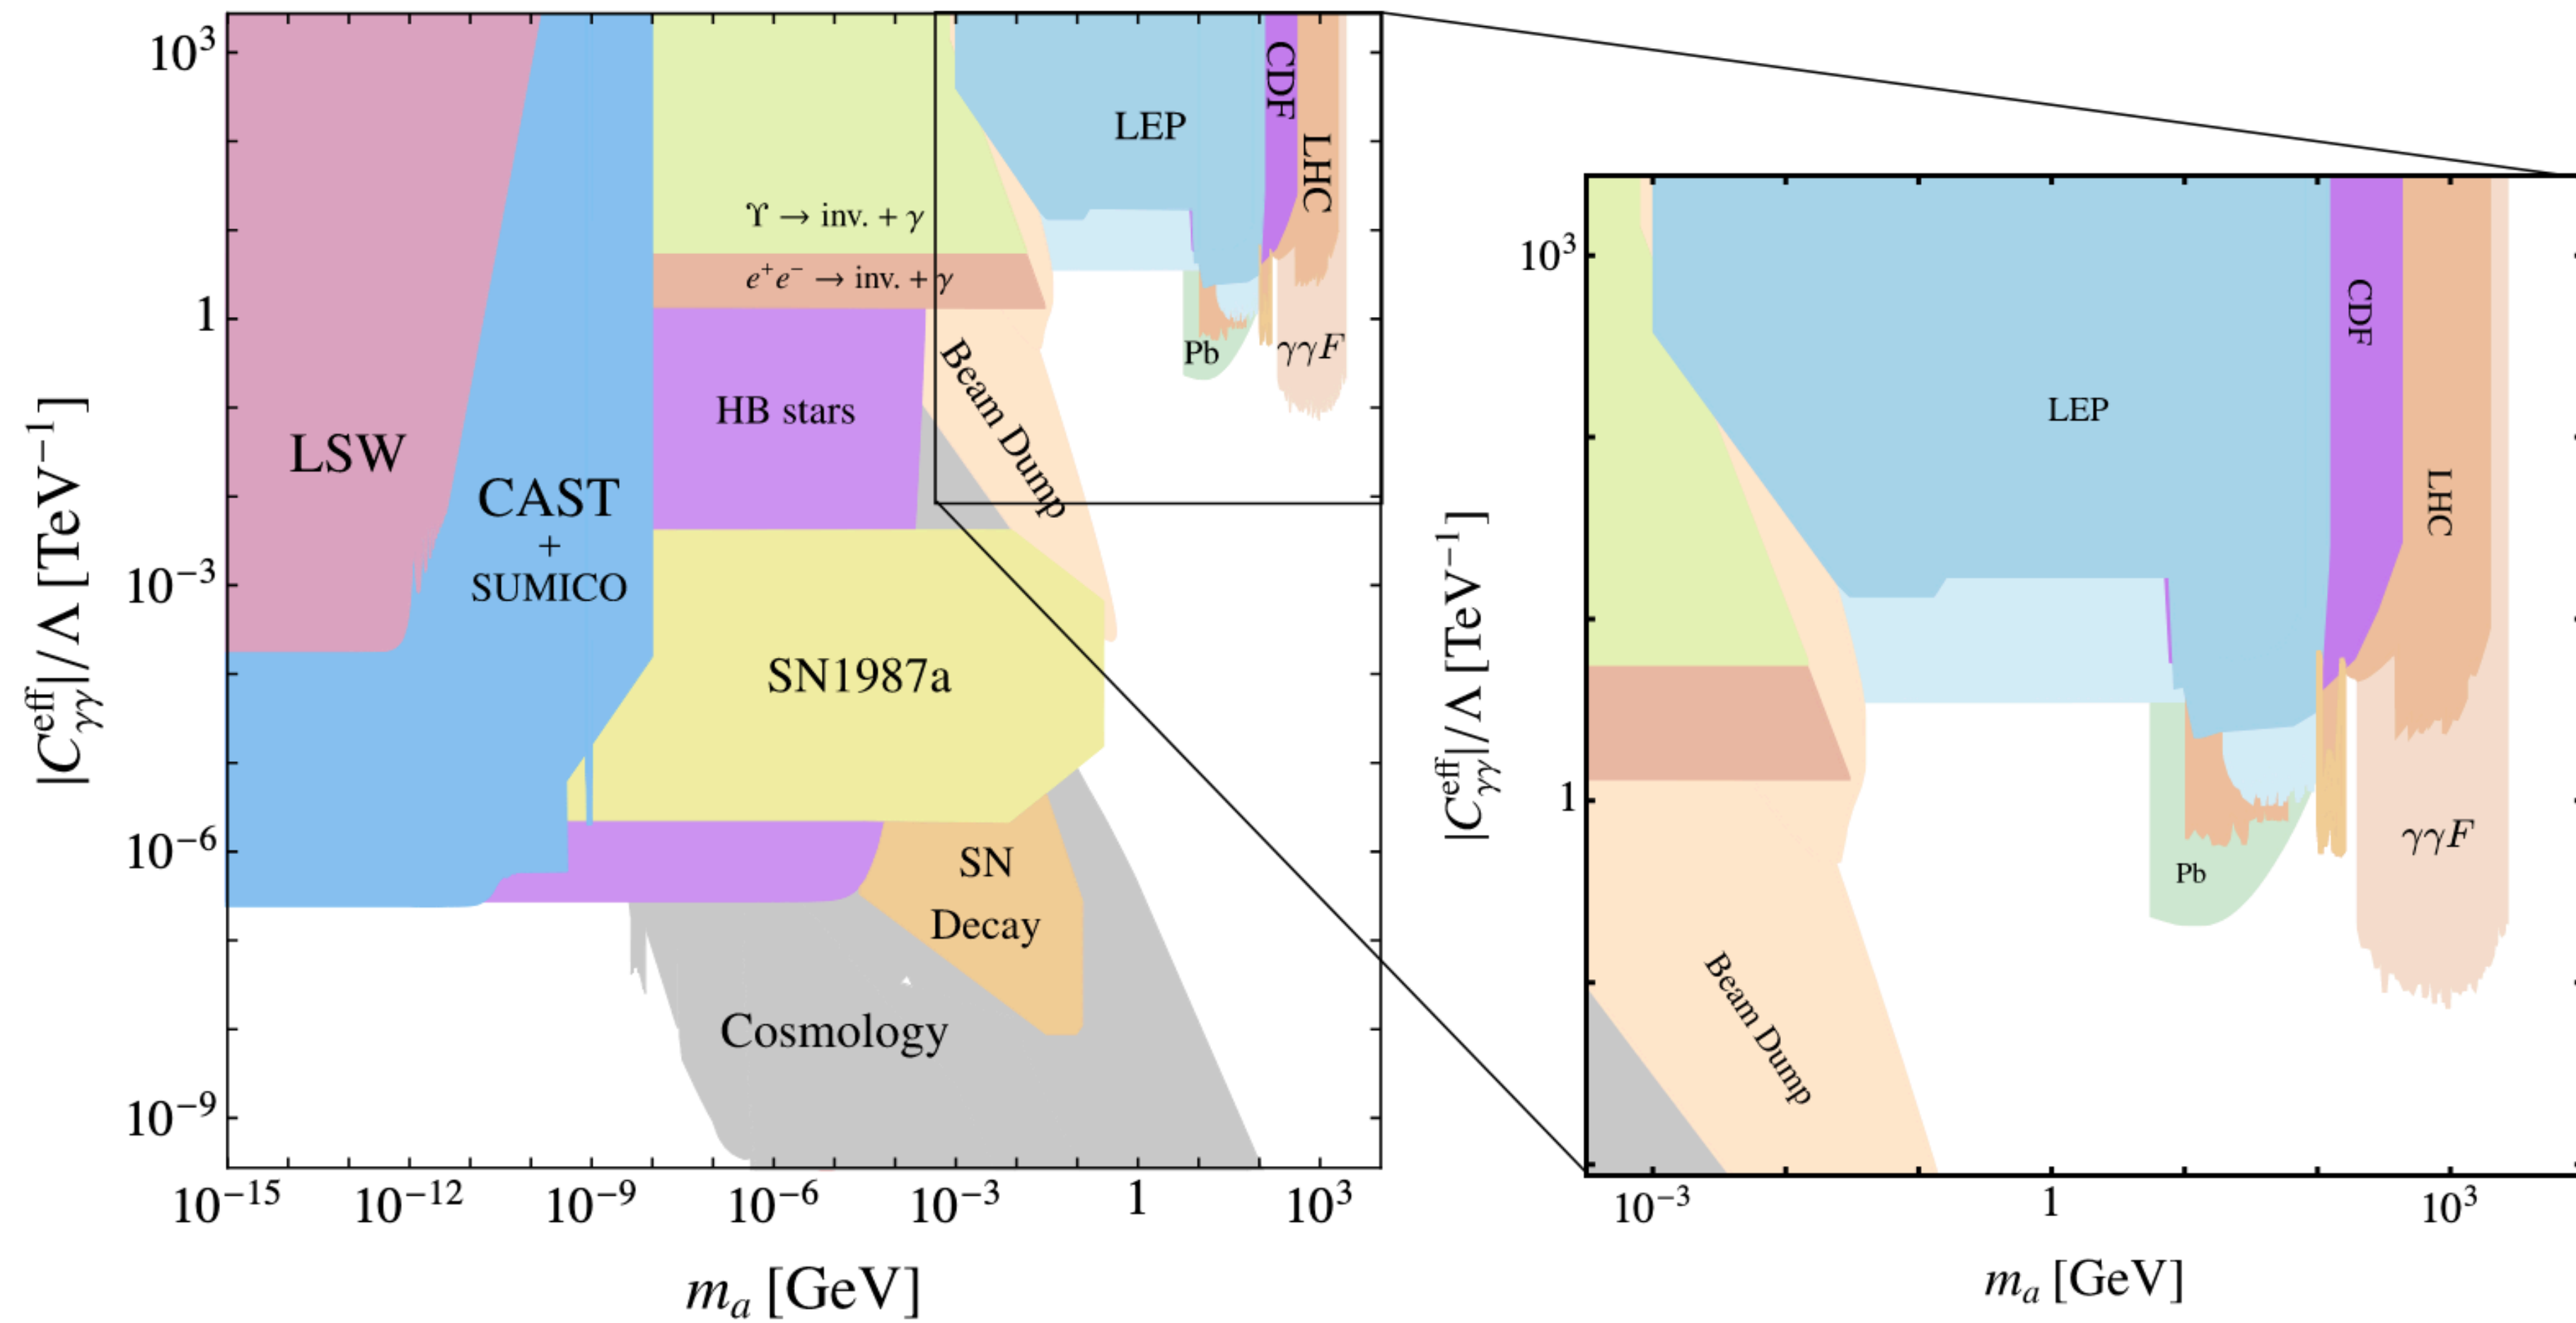

# Long-lived ALPs

- Commonly produced with a photon or a Z decaying into photons
- For small couplings and light ALPs, the ALP decay vertex can be considerably displaced from the production vertex  $\rightarrow$  LLP

Summary plot of constraints on the parameter space spanned by the ALP mass and ALP-photon coupling with enlarged display of the constraints from collider searches from [arXiv:1808.10323](https://arxiv.org/abs/1808.10323)

# 3. The Higgs boson

## To be more precise, its decays

- We are still getting to know the Higgs boson, the LHC is the only place to study it (for now)
- So far it looks SM-like but it still could be exotic and provide us with indications of what lies beyond the SM
- Exotic Higgs decays to long-lived particles are widely motivated in (for example)
  - **Twin Higgs** models, **Hidden Valley** models ([arXiv:1812.05588](https://arxiv.org/abs/1812.05588)), Higgsinos ([arXiv:1712.07135](https://arxiv.org/abs/1712.07135)), Higgs portal, dark glueball ([arXiv:1911.08721](https://arxiv.org/abs/1911.08721)) etc etc

Quiz stop #2!

Go to [www.menti.com](https://www.menti.com) and use the code 3134 9531

Now it is your turn: which LLPs or BSM models with LLPs are your favorite? you can pick three!

# As an experimentalist

**The study of long-lived particles offers something extra!**

- A whole catalogue of very exciting signatures!
- And experimentalist don't need to pick a model
- Just to guarantee that LLP signatures are properly identified and reconstructed
- Sadly, that is NOT EASY

# The technical challenges

daunting

# At the LHC

## We push the energy frontier

- As we reach higher and higher energies, we gain access to more massive particles
  - That in turn are shorter and shorter-lived

# Main offenders

The Higgs boson  
2012 - LHC  
Sort-Lived  
 $10^{-22}$  seconds  
You blink and you miss it!

The top quark  
1995 - Tevatron  
Sort-Lived  
 $10^{-25}$  seconds  
So short-lived it does not even have time to form hadrons!

# Detecting particles

## At high-energy colliders

E.g. the Higgs boson at the LHC:

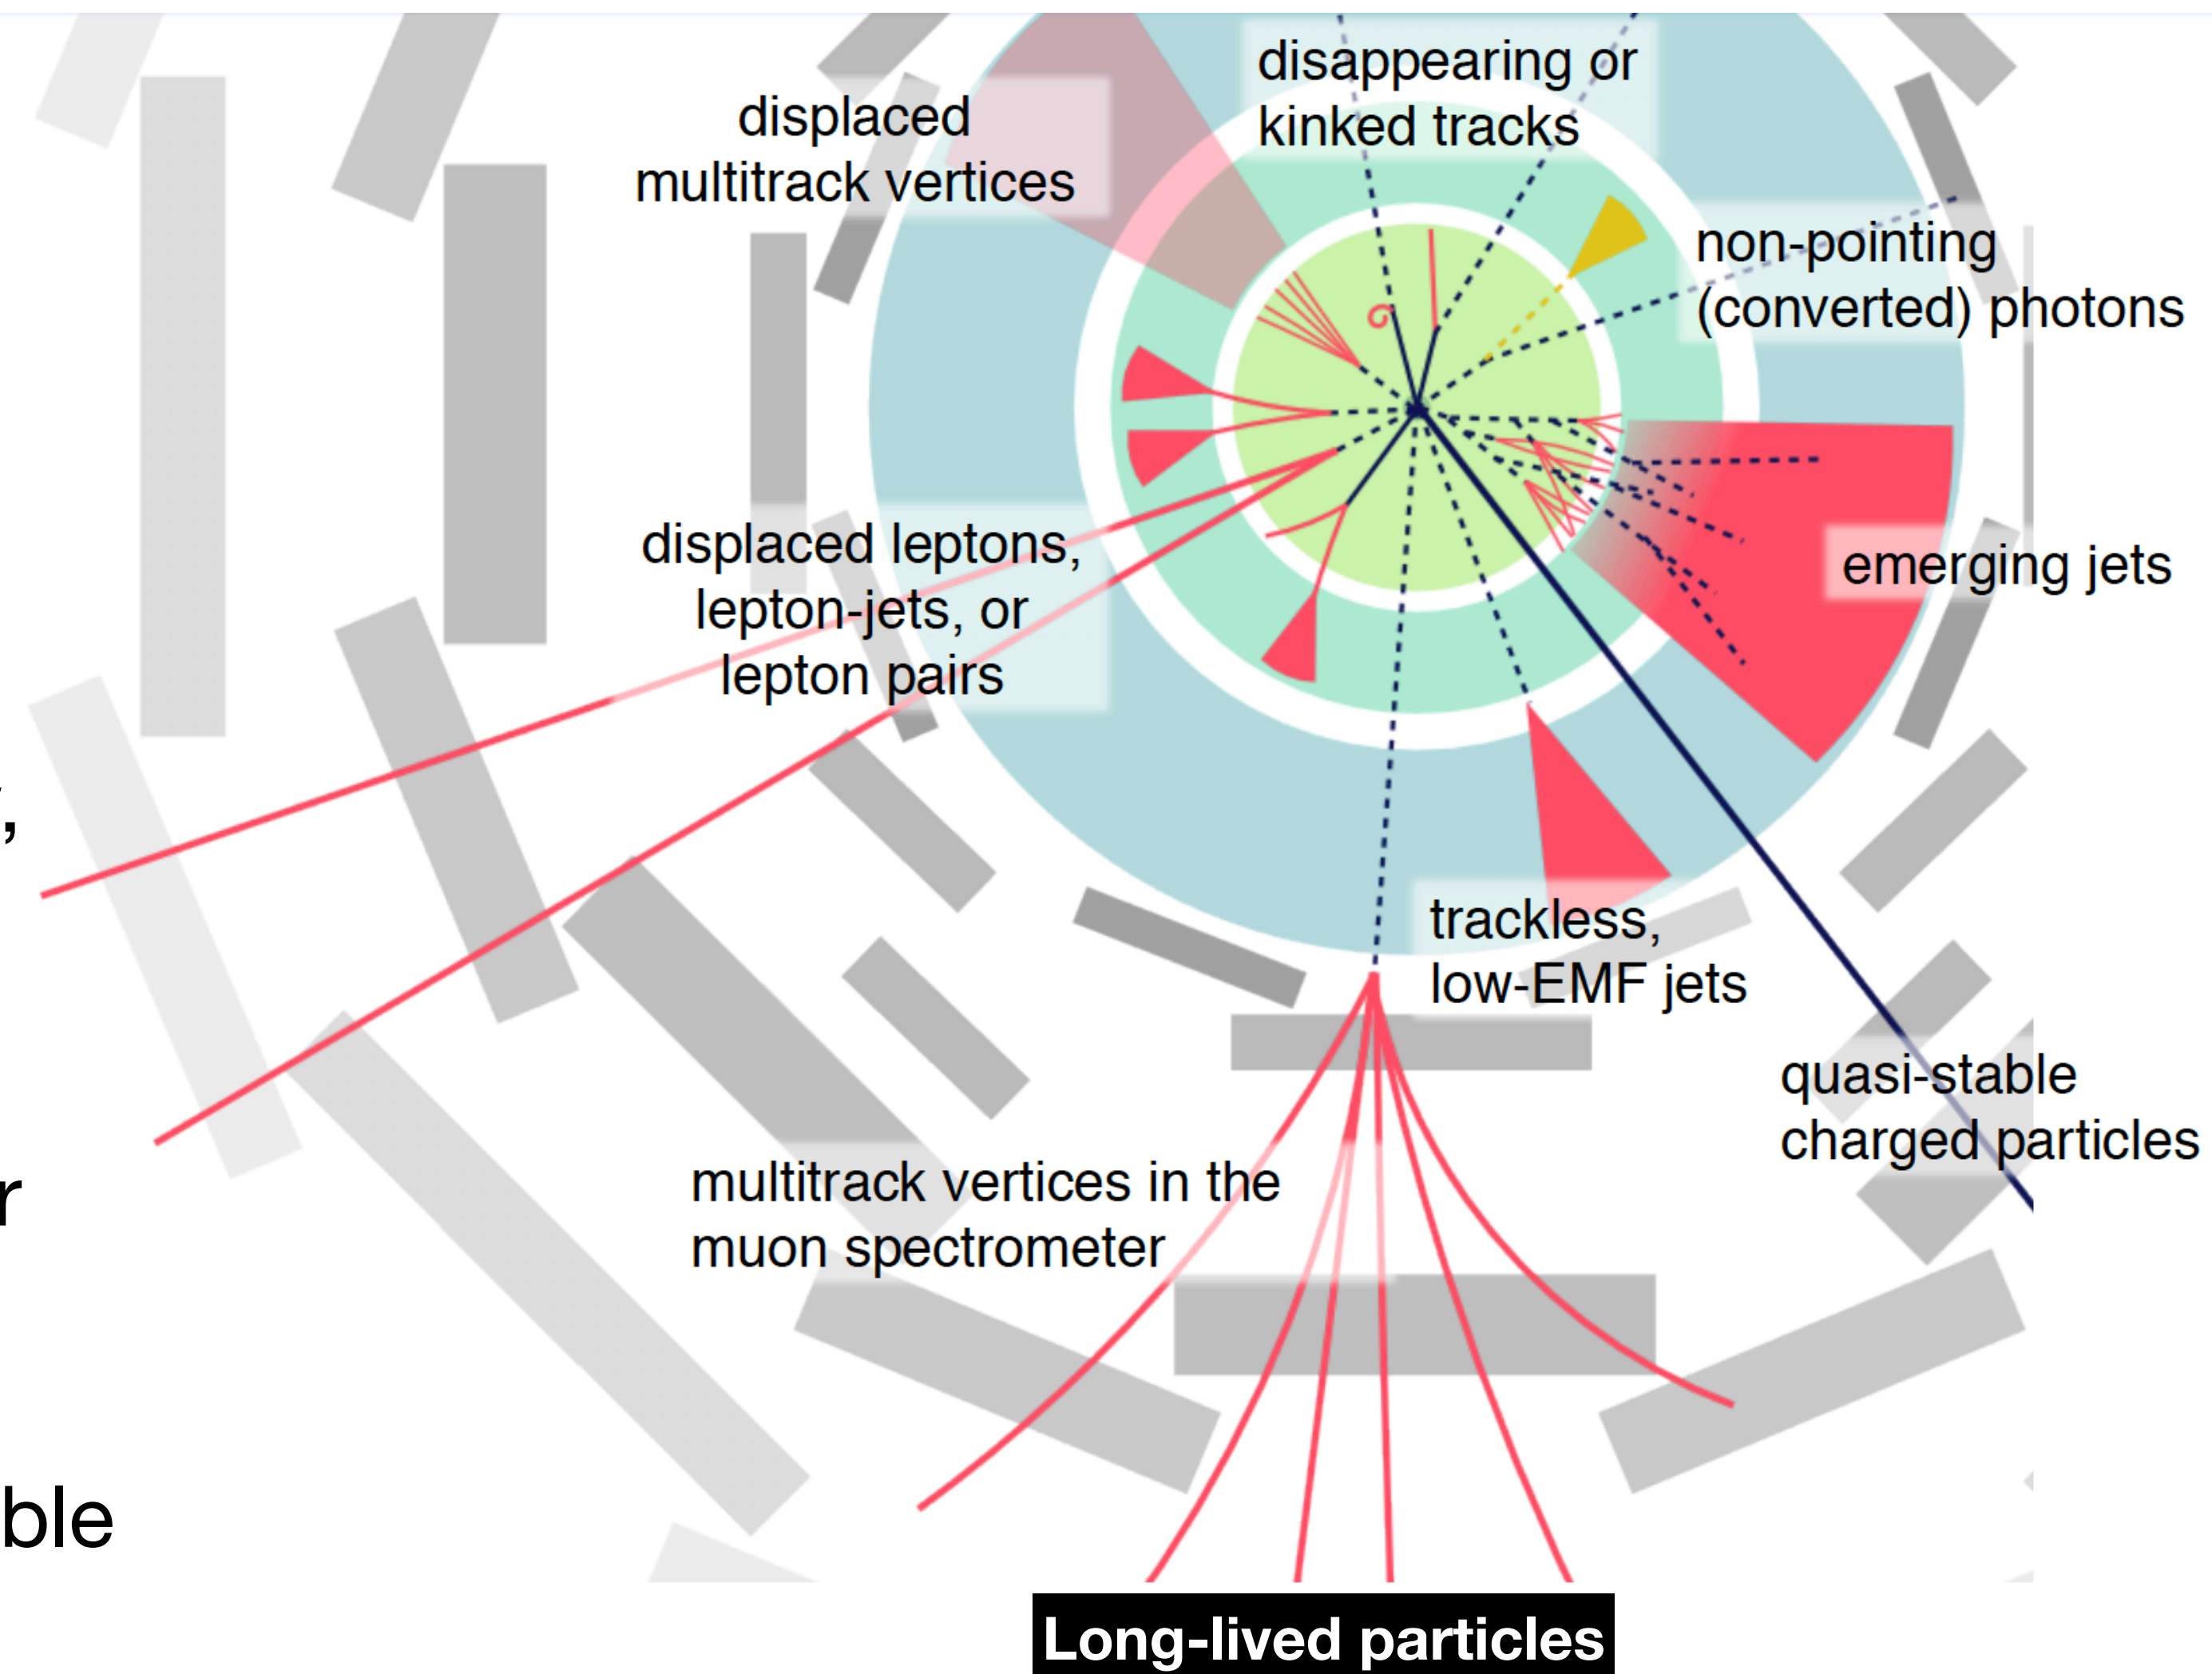

- A Higgs boson is produced and decays  $10^{-22}$  seconds after
- It often decays into two Z bosons, each of them decaying in about  $10^{-25}$  s in e.g. a couple of muons each
- In practice this means that we see 4 muons coming from the collision point

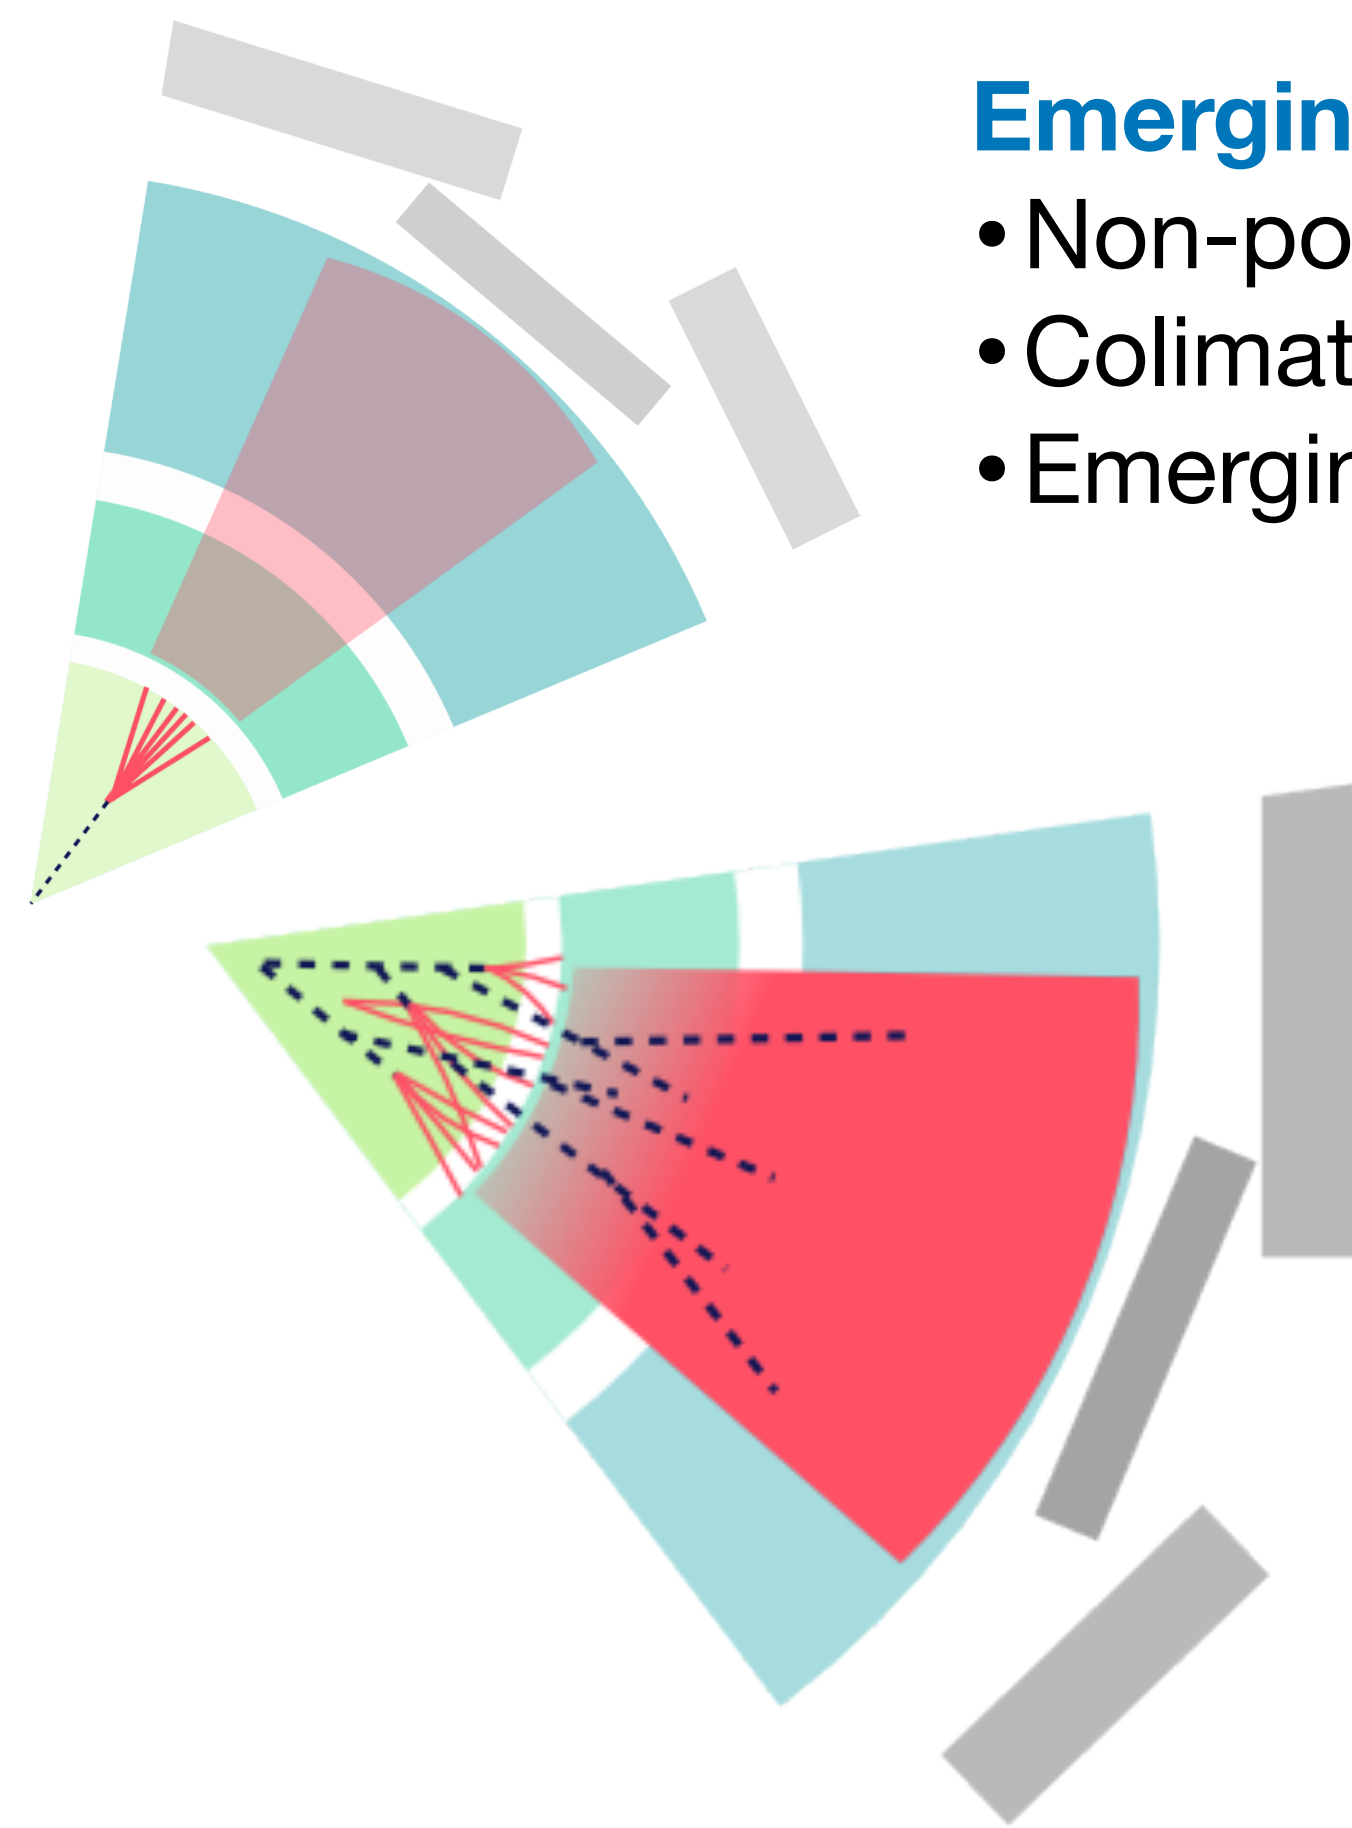

**Our detectors, trigger, and reconstruction are optimized for that!**

- Long-lived particle searches probe unconventional signatures
  - Displaced, disappearing, emerging, slow, stopped...
- This is a curse and a blessing
  - It makes them clearly different from other processes
    - **Easy to spot! Background free!**
  - It also could make them potentially invisible to current data-acquisition methods
    - **Hard to spot! We may be throwing them away!**

## Emerging/weird

- Non-pointing photons (Calo)
- Colimated objects (Tracker, Calo)
- Emerging jets (Tracker, Calo)

## More Tracking component

- Anomalous  $dE/dx$  track
- Fractionally charged, Multicharged particles..
- Short (disappearing, kinked) tracks

## Displaced/Delayed stuff

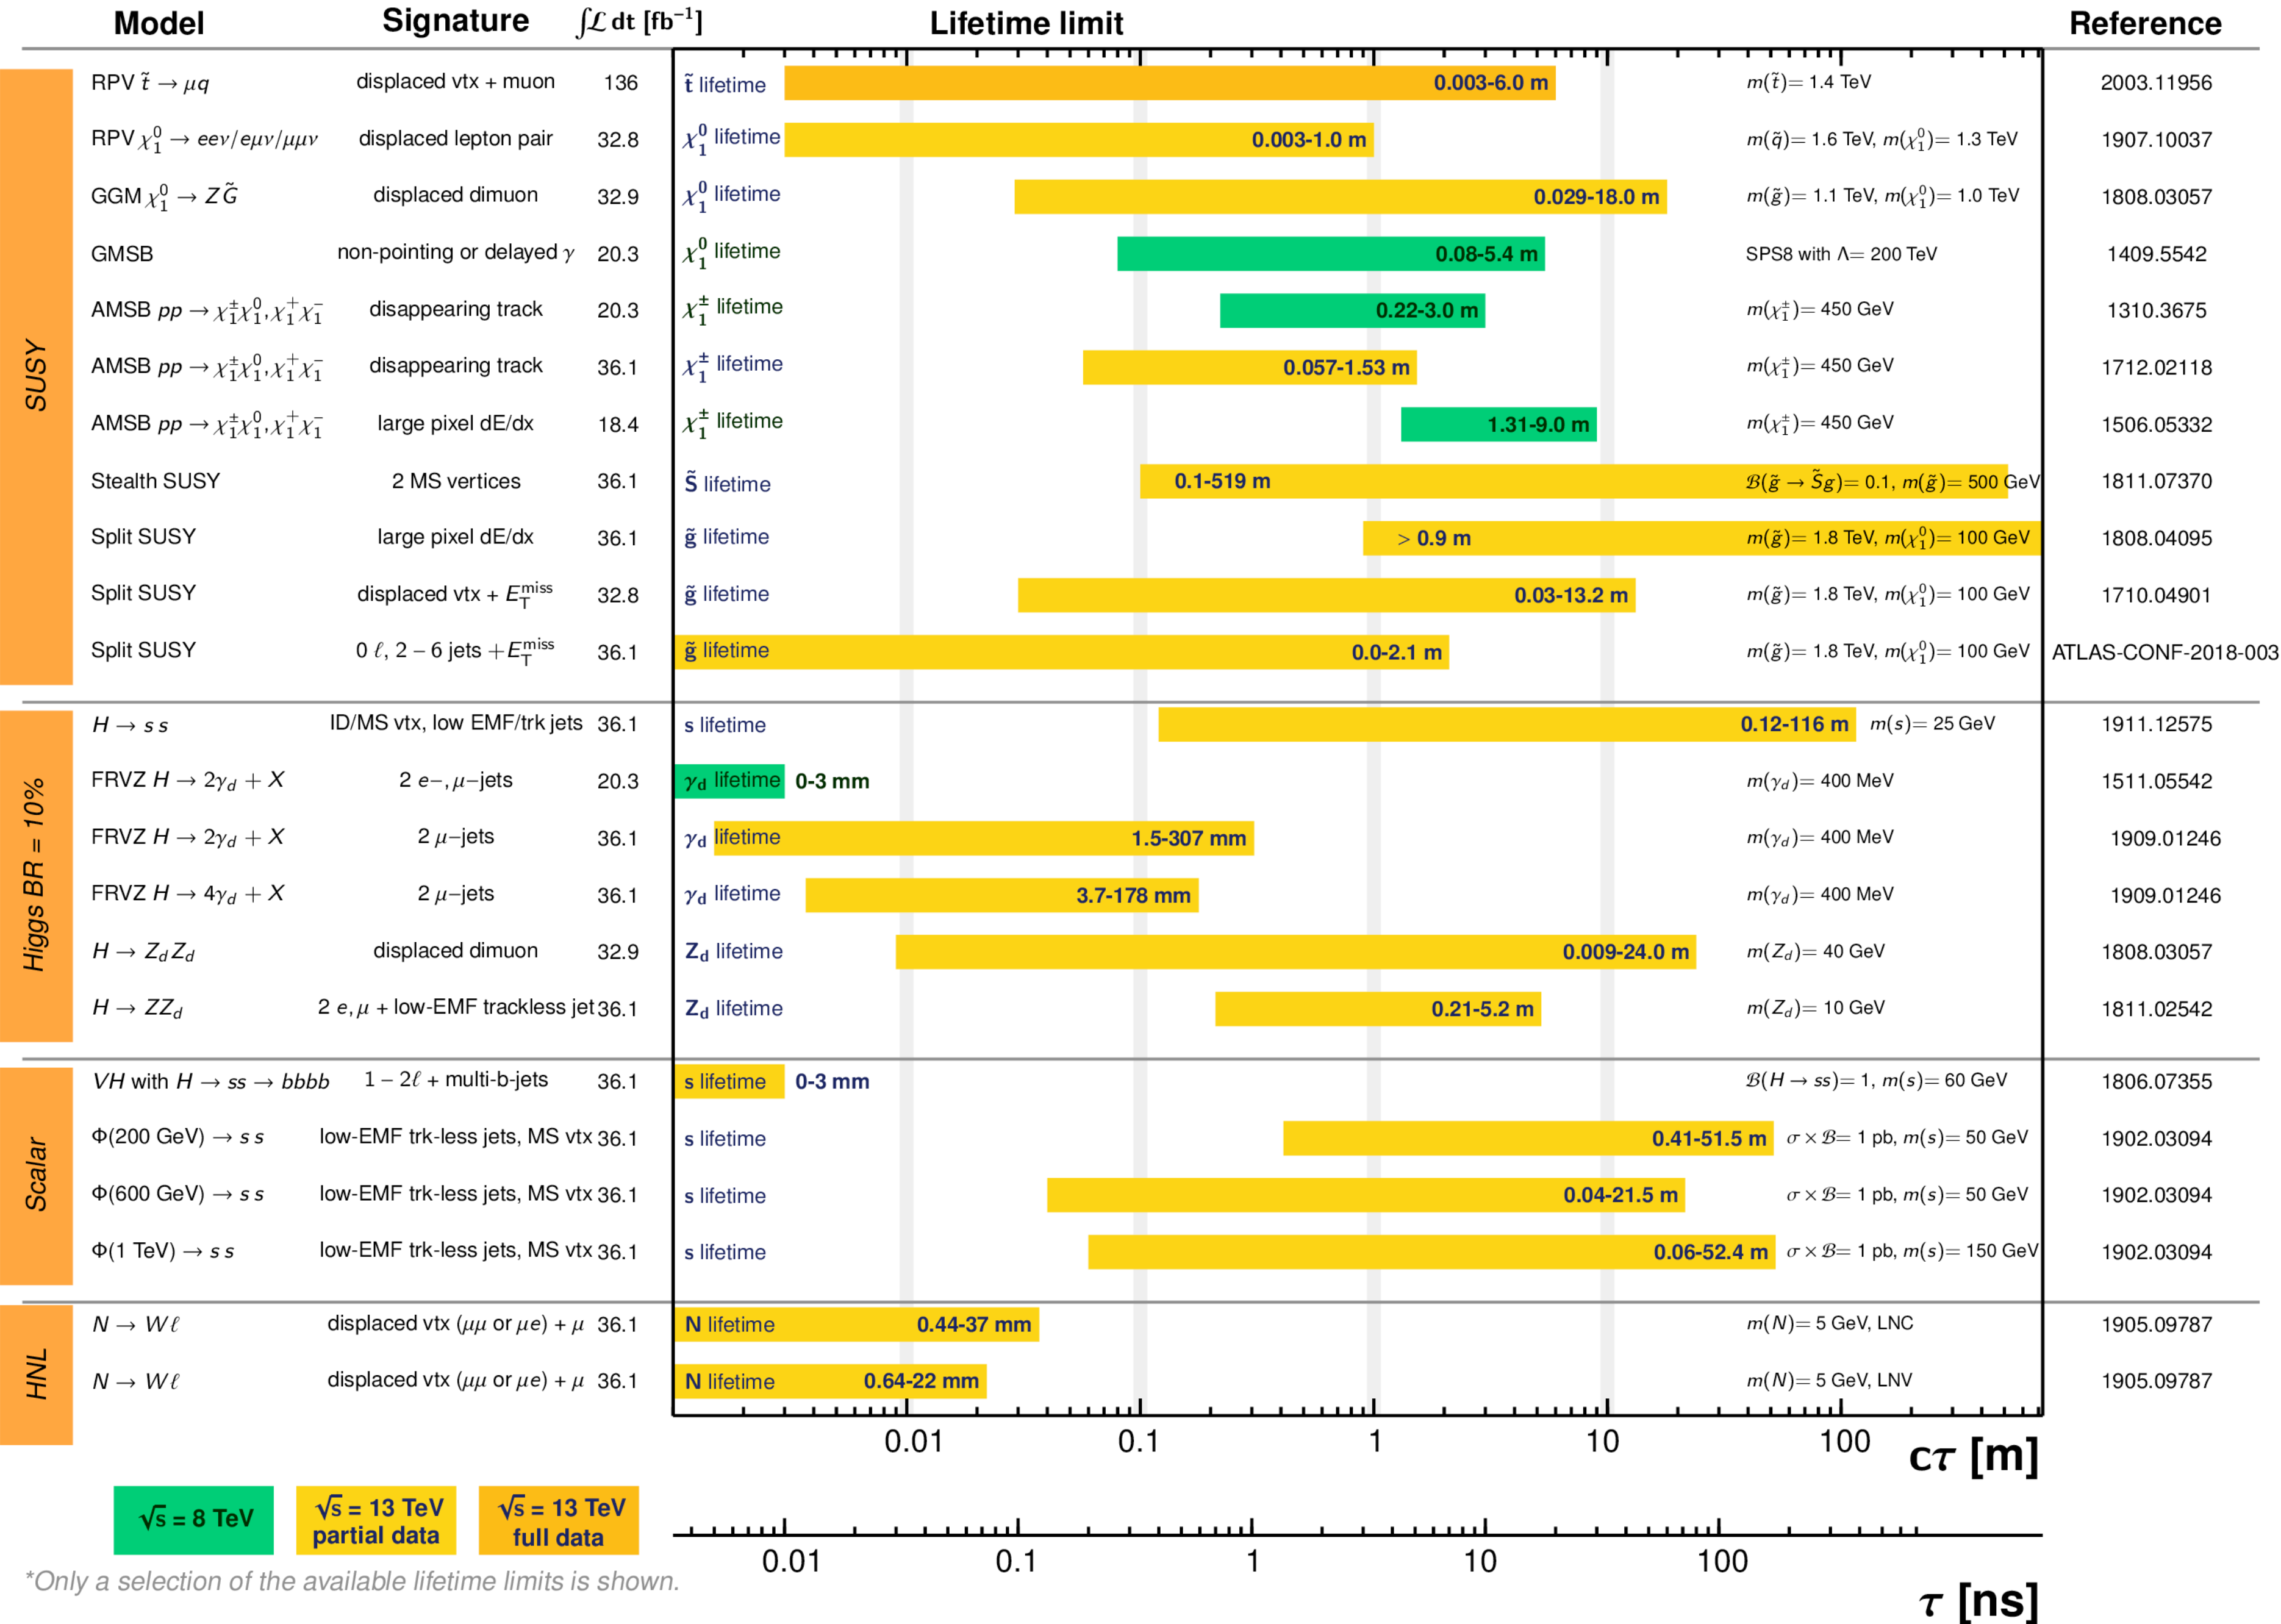

- Displaced vertices and tracks (Tracker, Calo)
- Delayed/displaced jets (Tracker, Calo)
- Stopped particle decay (Timing!)

# Are we working on this?

- **Yes**, since the start of the LHC, at LEP, and the Tevatron...
- Up until 2016 however, LLP searches were considered fringe, today they make up less than 10% of our exotic searches
- But they are starting to pick up a lot of interest
  - LHC Long-lived Particles Working Group (LHC LLP WG)
    - <https://lpcc.web.cern.ch/lhc-llp-wg>
  - LHC Long-lived particle community workshops
    - <https://longlivedparticles.web.cern.ch/>

# Paradigm shift

- Looking for this kind of signatures STILL represents a paradigm shift from the usual approach to hunting for new physics
- Implies exploiting the detectors in ways they were not designed for

# Roadblocks

- Need for **specialized reconstruction algorithms**
  - Especially clear in the **Tracker** (less utilized subdetector in LLP so far)
- Very low background searches, but affected by instrumental effects, not well-modelled in the simulation
- Last, but not least: **THE TRIGGER!**

# Trigger matters

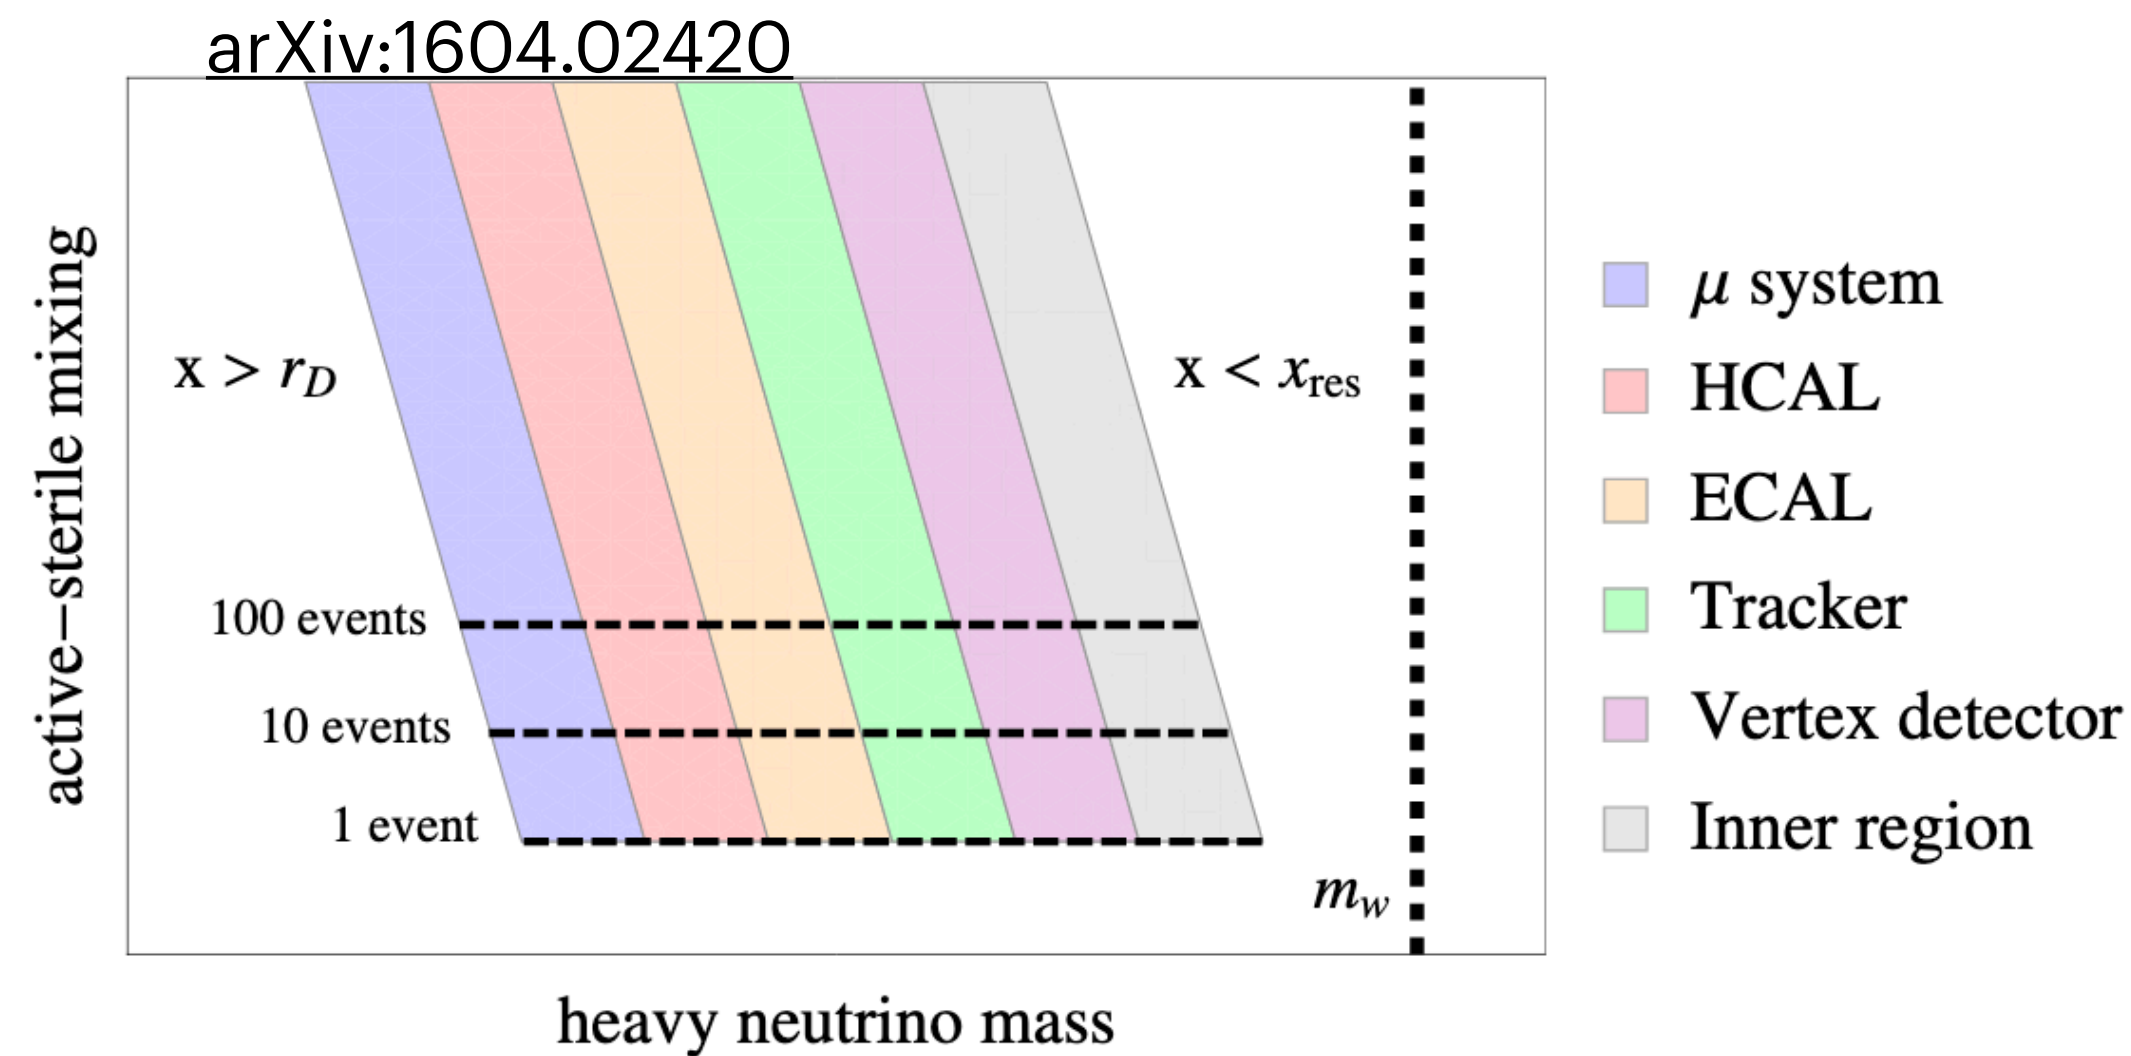

- We have 1.7 billion collisions per second and ATLAS and CMS cannot record and process all of them
  - Complicated Trigger and Data Acquisition systems decide what to keep
- ATLAS does this in two stages
  - Level-1 hardware trigger (calorimeter and muon detectors). The decision to keep an event is made less than  $2.5\mu\text{s}$ 
    - It saves up to 100,000 events/s for the next step
  - High-Level Trigger (HLT), software based
    - Does some reconstruction, selects  $\sim 1000$  events/s for offline analysis.

# Filtering out things you do not want

- In the case of LLP, if you do not filter them “in” then you may be actively filtering them “out”
- Most public LLP analyses use custom trigger paths
  - + Relying on objects produced together with the LLP (MET, leptons, jets)
    - Most trigger reconstruction algorithms assume prompt particles
    - There is no track information at decision level, so we could be missing many interesting events
- Are we missing LLPs decaying in the tracker?
  - Probably yes

# This won't be different at future colliders

Sensitivity of different detector components to HNL as a function of the mixing parameter and mass

- At this point we have two ways to go:
  - Design the future detectors as usual and then try to make the best out of them for LLPs
    - which can be done but won't be easy as we know from the experience at the LHC -and before-
  - Design the future detectors with LLP in mind, prioritising for example displaced tracking and timing, and budgeting for unexpected signals
    - which can bring up not only a boost for these searches but also **innovation**

# The next collider

Is closer than one would think

# The High-luminosity upgrade of the LHC

## Coming up about 2027

# How does a HL-LHC collision look like?

Short answer: **BUSY**

- Very high pile-up, luminosity 7.5x design
  - ~200 pp collisions are expected every 25 ns
  - Vs ~36-37 in Run-2
- Neither track reconstruction or trigger are going to get any easier

# HL-LHC for long-lived particles

## • New functionalities

- **Track triggers** (arXiv:1907.09846): e.g. trigger on displaced muons from the same vertex to find dark photons (arXiv:1705.04321)
- Better **timing information**: using timing information to target pair-produced LLPs significantly delayed (arXiv:1805.05957)

CERN November 2015

# HL-LHC opens the door to something else

## When even ATLAS is not big enough

- Some long-lived particles could be long enough to decay outside the LHC detectors
- And in fact not even ATLAS is big enough cover the whole lifetime gap
- We can supplement them with external detectors
  - Would catch very long decay lengths and more importantly: will have little background

# HL-LHC: Dedicated experiments

- Complementary instrumentation in the caverns offering low background environments
  - **FASER**: (approved)  $\sim 1 \text{ m}^3$  480 m downstream from the ATLAS interaction point (on-axis)
  - **MATHUSLA**: (proposed) large-scale surface detector instrumenting  $\sim 8 \times 10^5 \text{ m}^3$  above ATLAS or CMS (off-axis)
  - **CODEX-b**: (proposed)  $\sim 10^3 \text{ m}^3$  detector in the LHCb cavern (off-axis)
  - **AL3X**: (proposed) cylindrical  $\sim 900 \text{ m}^3$  detector inside the L3 magnet and the time-projection chamber of the ALICE experiment
  - **ANUBIS**: (proposed)  $1 \times 1 \text{ m}^2$  units on top of ATLAS/CMS (off-axis)

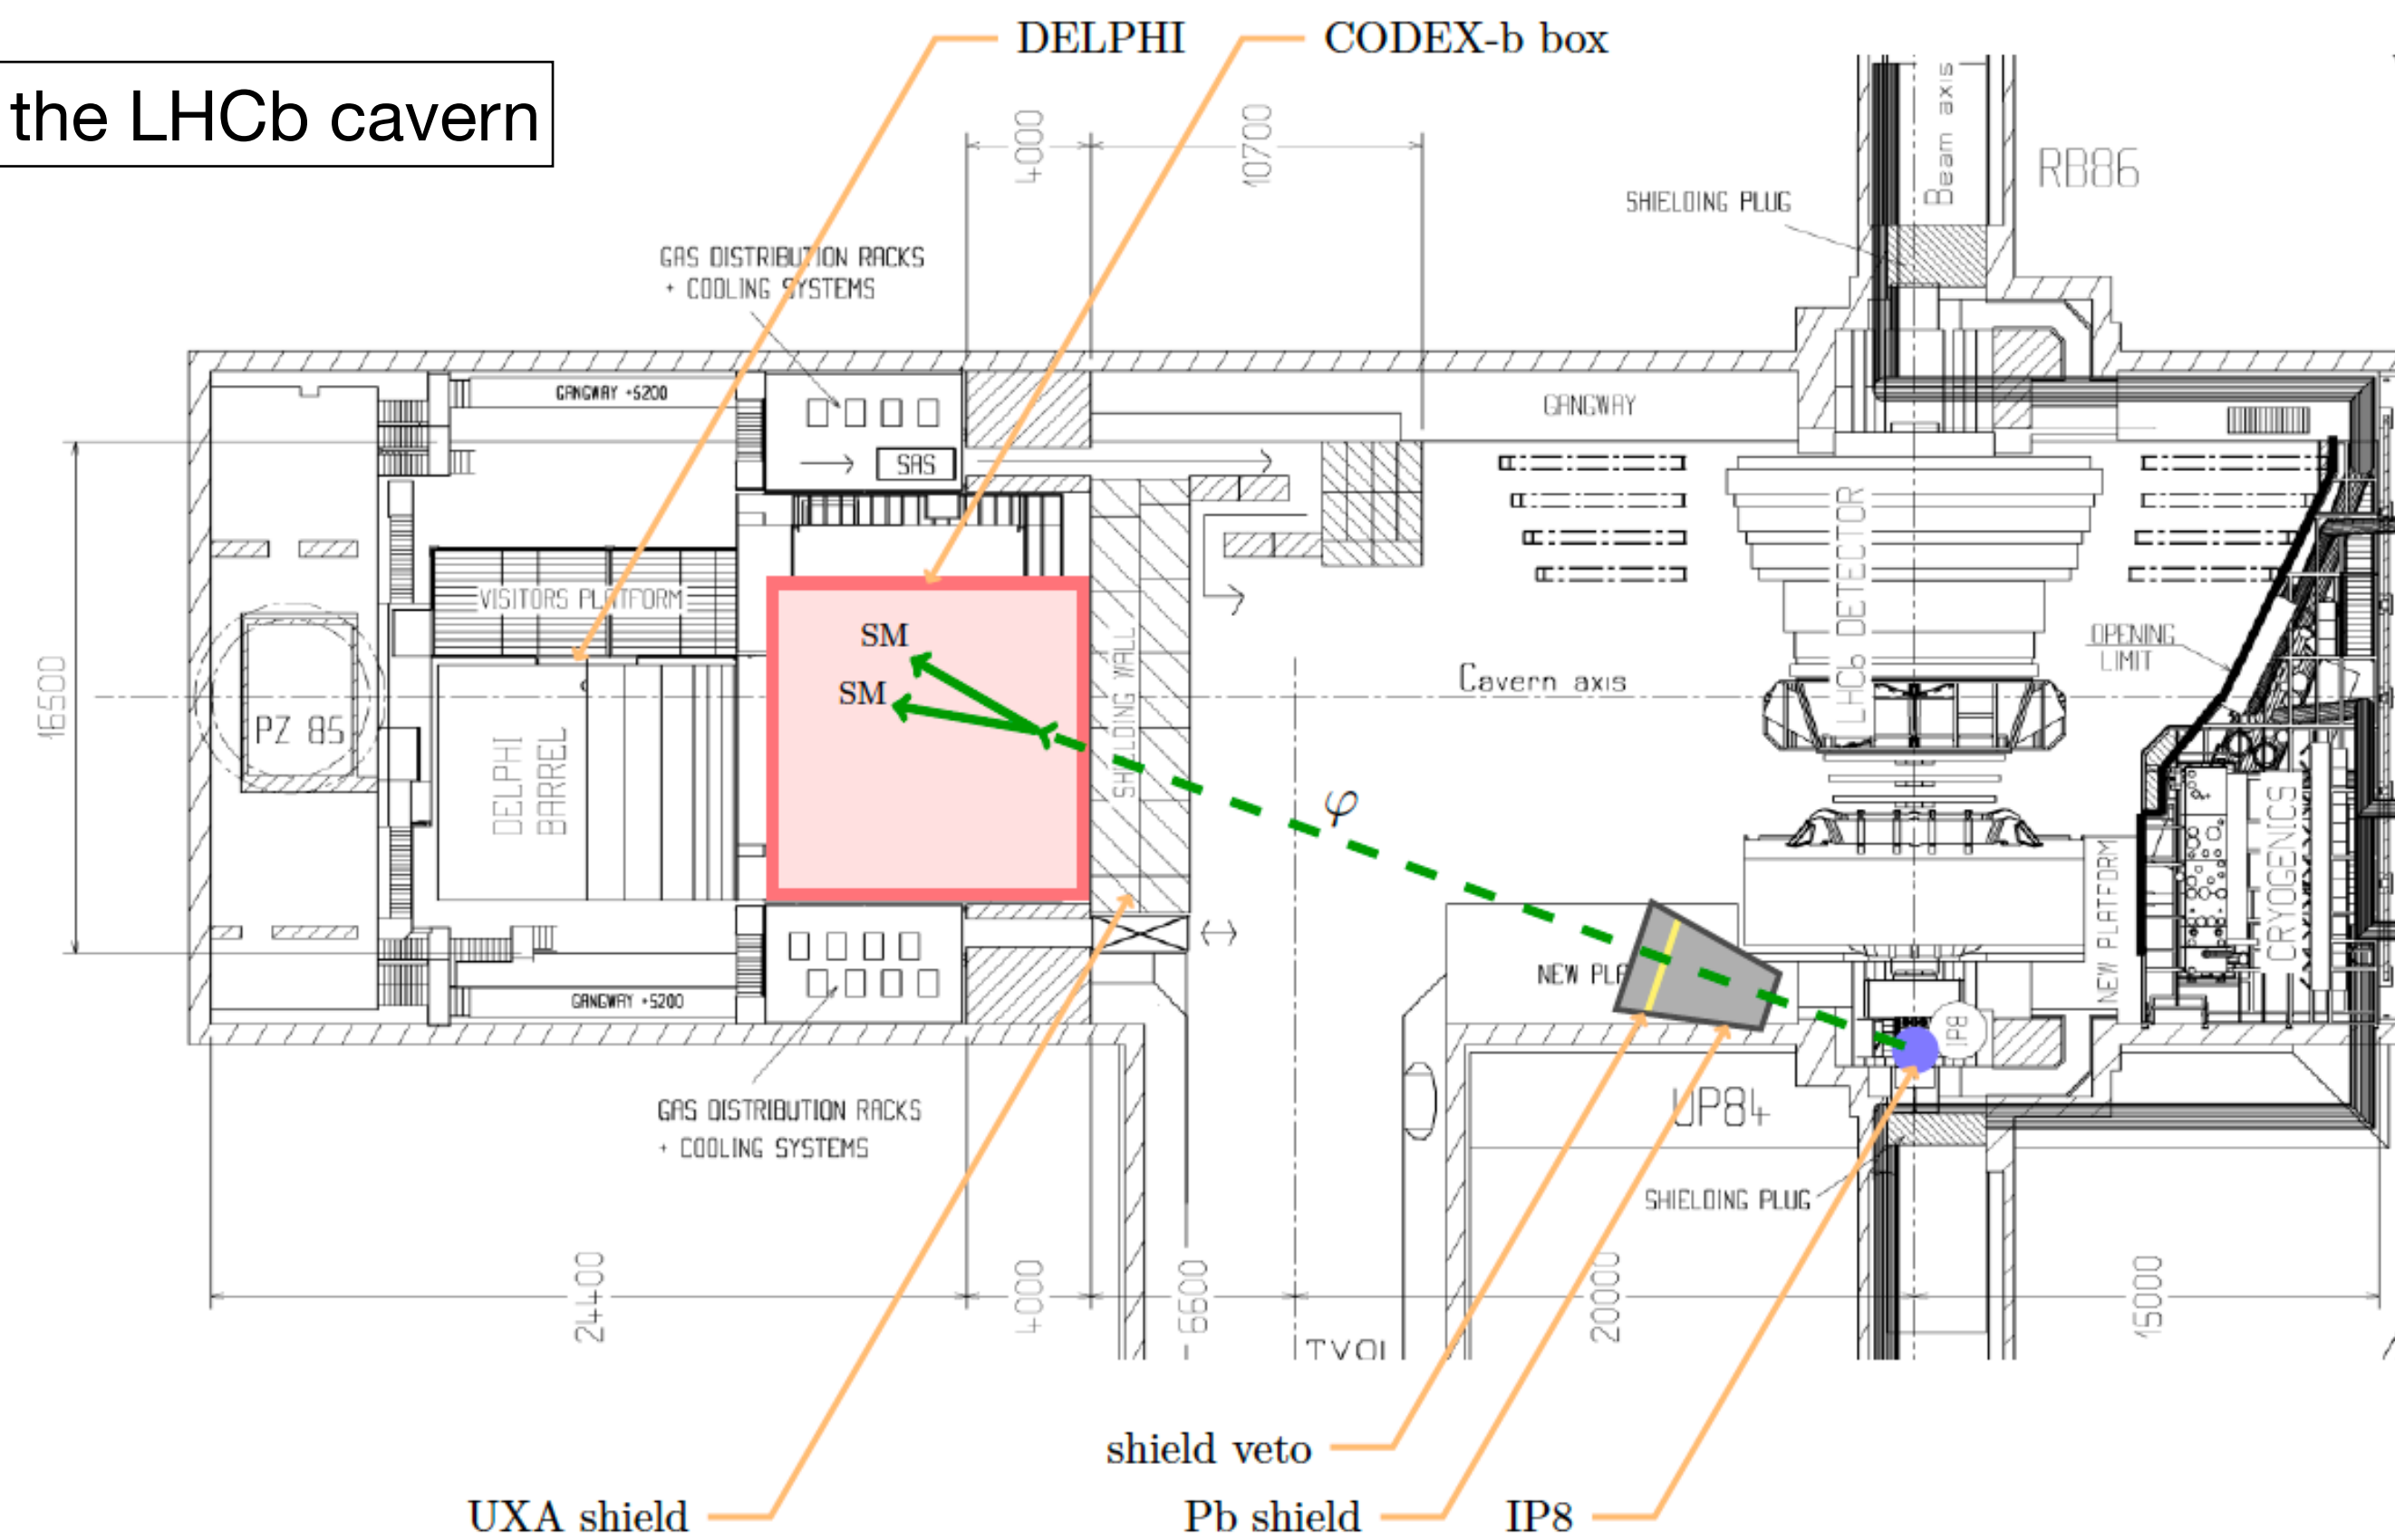

FASER installation this spring  
<https://cds.cern.ch/record/2756507?ln=en>

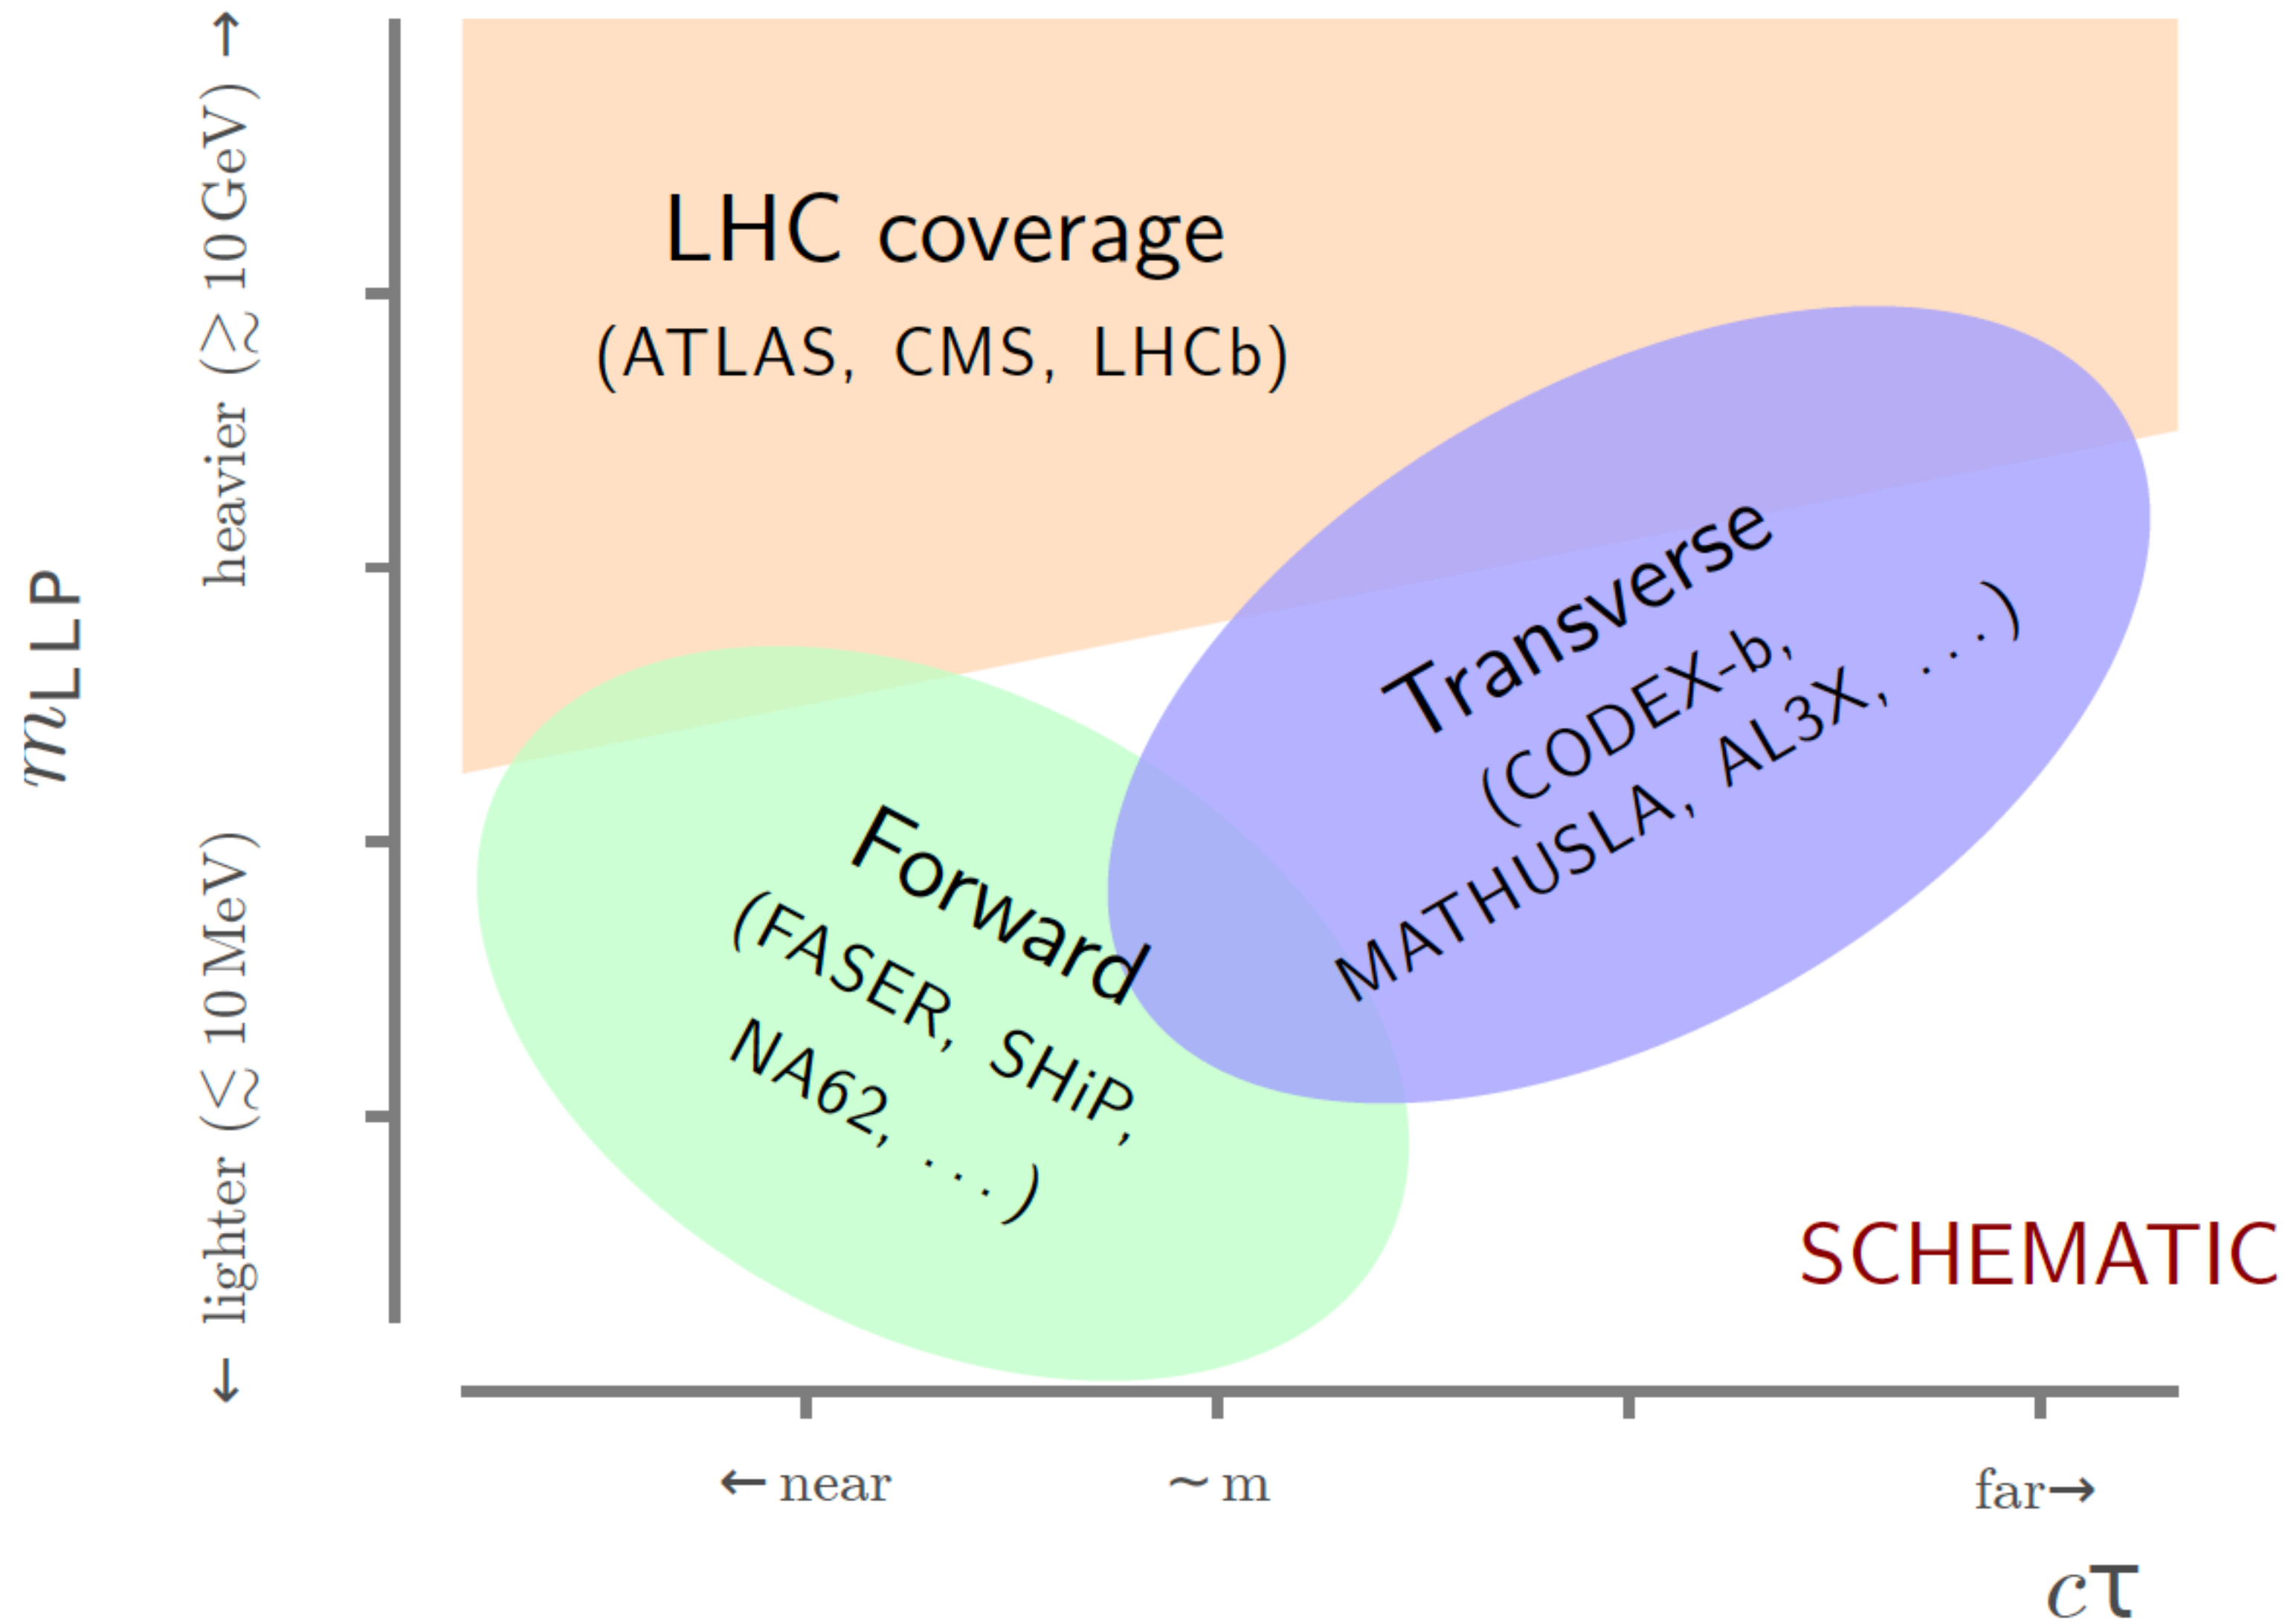

Plan of CODEX-b in the LHCb cavern

# More LLP experiments

- Beam-dump experiments:
  - **SHiP:** (proposed) would require dedicated operation with the 400 GeV SPS beam
- Experiments for exotic electromagnetic charge:
  - **MilliQan:** (demonstrator taking data) searching for millicharged particles in the drainage gallery of CMS
  - **MoEDAL:** (running) looking for highly ionizing particles like magnetic monopoles at LHCb alongside MAPP

- ATLAS/CMS upgrades for the HL-LHC will provide new functionalities
- External detectors off and on-axis could extend the LLP reach
- Beam bump experiments could extend the search for low-mass models

**And then?**

# We do not know yet

Quiz stop #3!

# What future collider would you go for?

# The European Strategy for Particle Physics

## 2020 Update

- *“An electron-positron Higgs factory is the highest-priority next collider. For the longer term, the European particle physics community has the ambition to operate a proton-proton collider at the highest achievable energy. [...]”*
- *“Europe, together with its international partners, should investigate the technical and financial feasibility of a future hadron collider at CERN with a centre-of-mass energy of at least 100 TeV and with an electron-positron Higgs and electroweak factory as a possible first stage. Such a feasibility study of the colliders and related infrastructure should be established as a global endeavor [...]”*

# An e<sup>+</sup>e<sup>-</sup> circular collider could be fantastic for LLP

## Especially for HNL

# Complementarity

Exclusion limits for ALPs coupled to photons. All curves correspond to 90% CL exclusion limits, except for LHeC/FCC-eh (95% CL exclusion limits), FCC-ee (observation of four signal events) and FCC-hh (observation of 100 signal events).

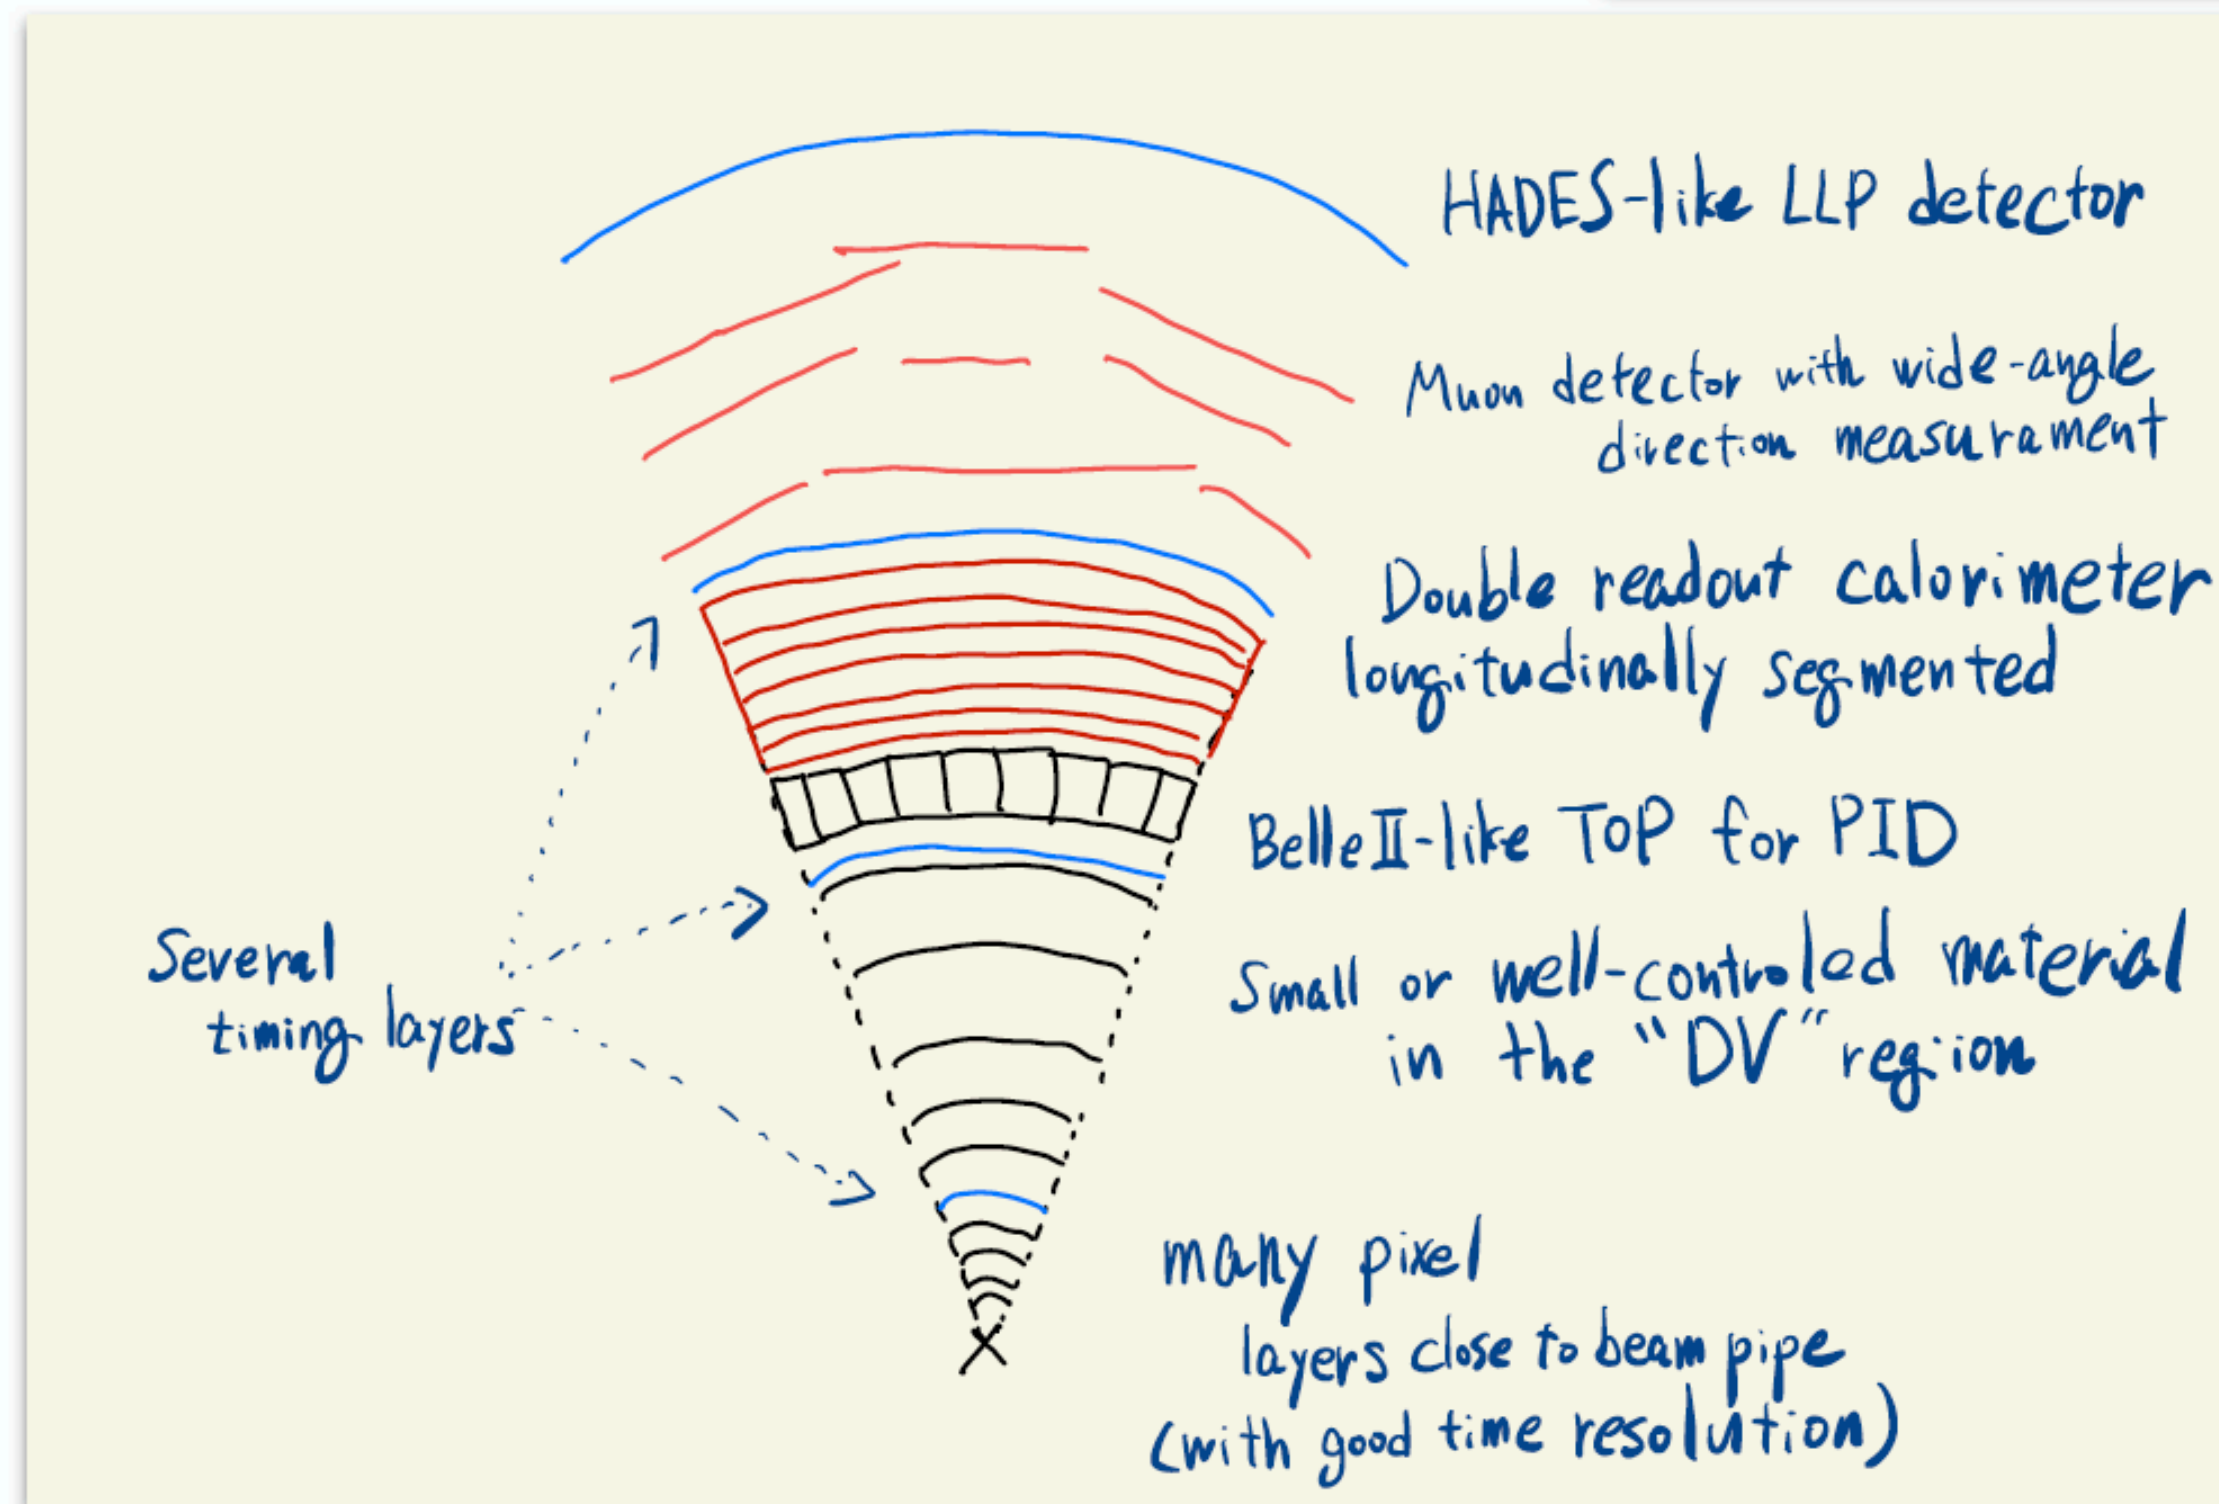

From the [Briefing Book](#)

- Different colliders offer sensitivity to different parameters in different models
- The key word is **complementarity**
- Certain colliders offer higher energy, other cleaner environments, access to different ranges of mass/couplings
- **Many challenges related to LLP will be common**

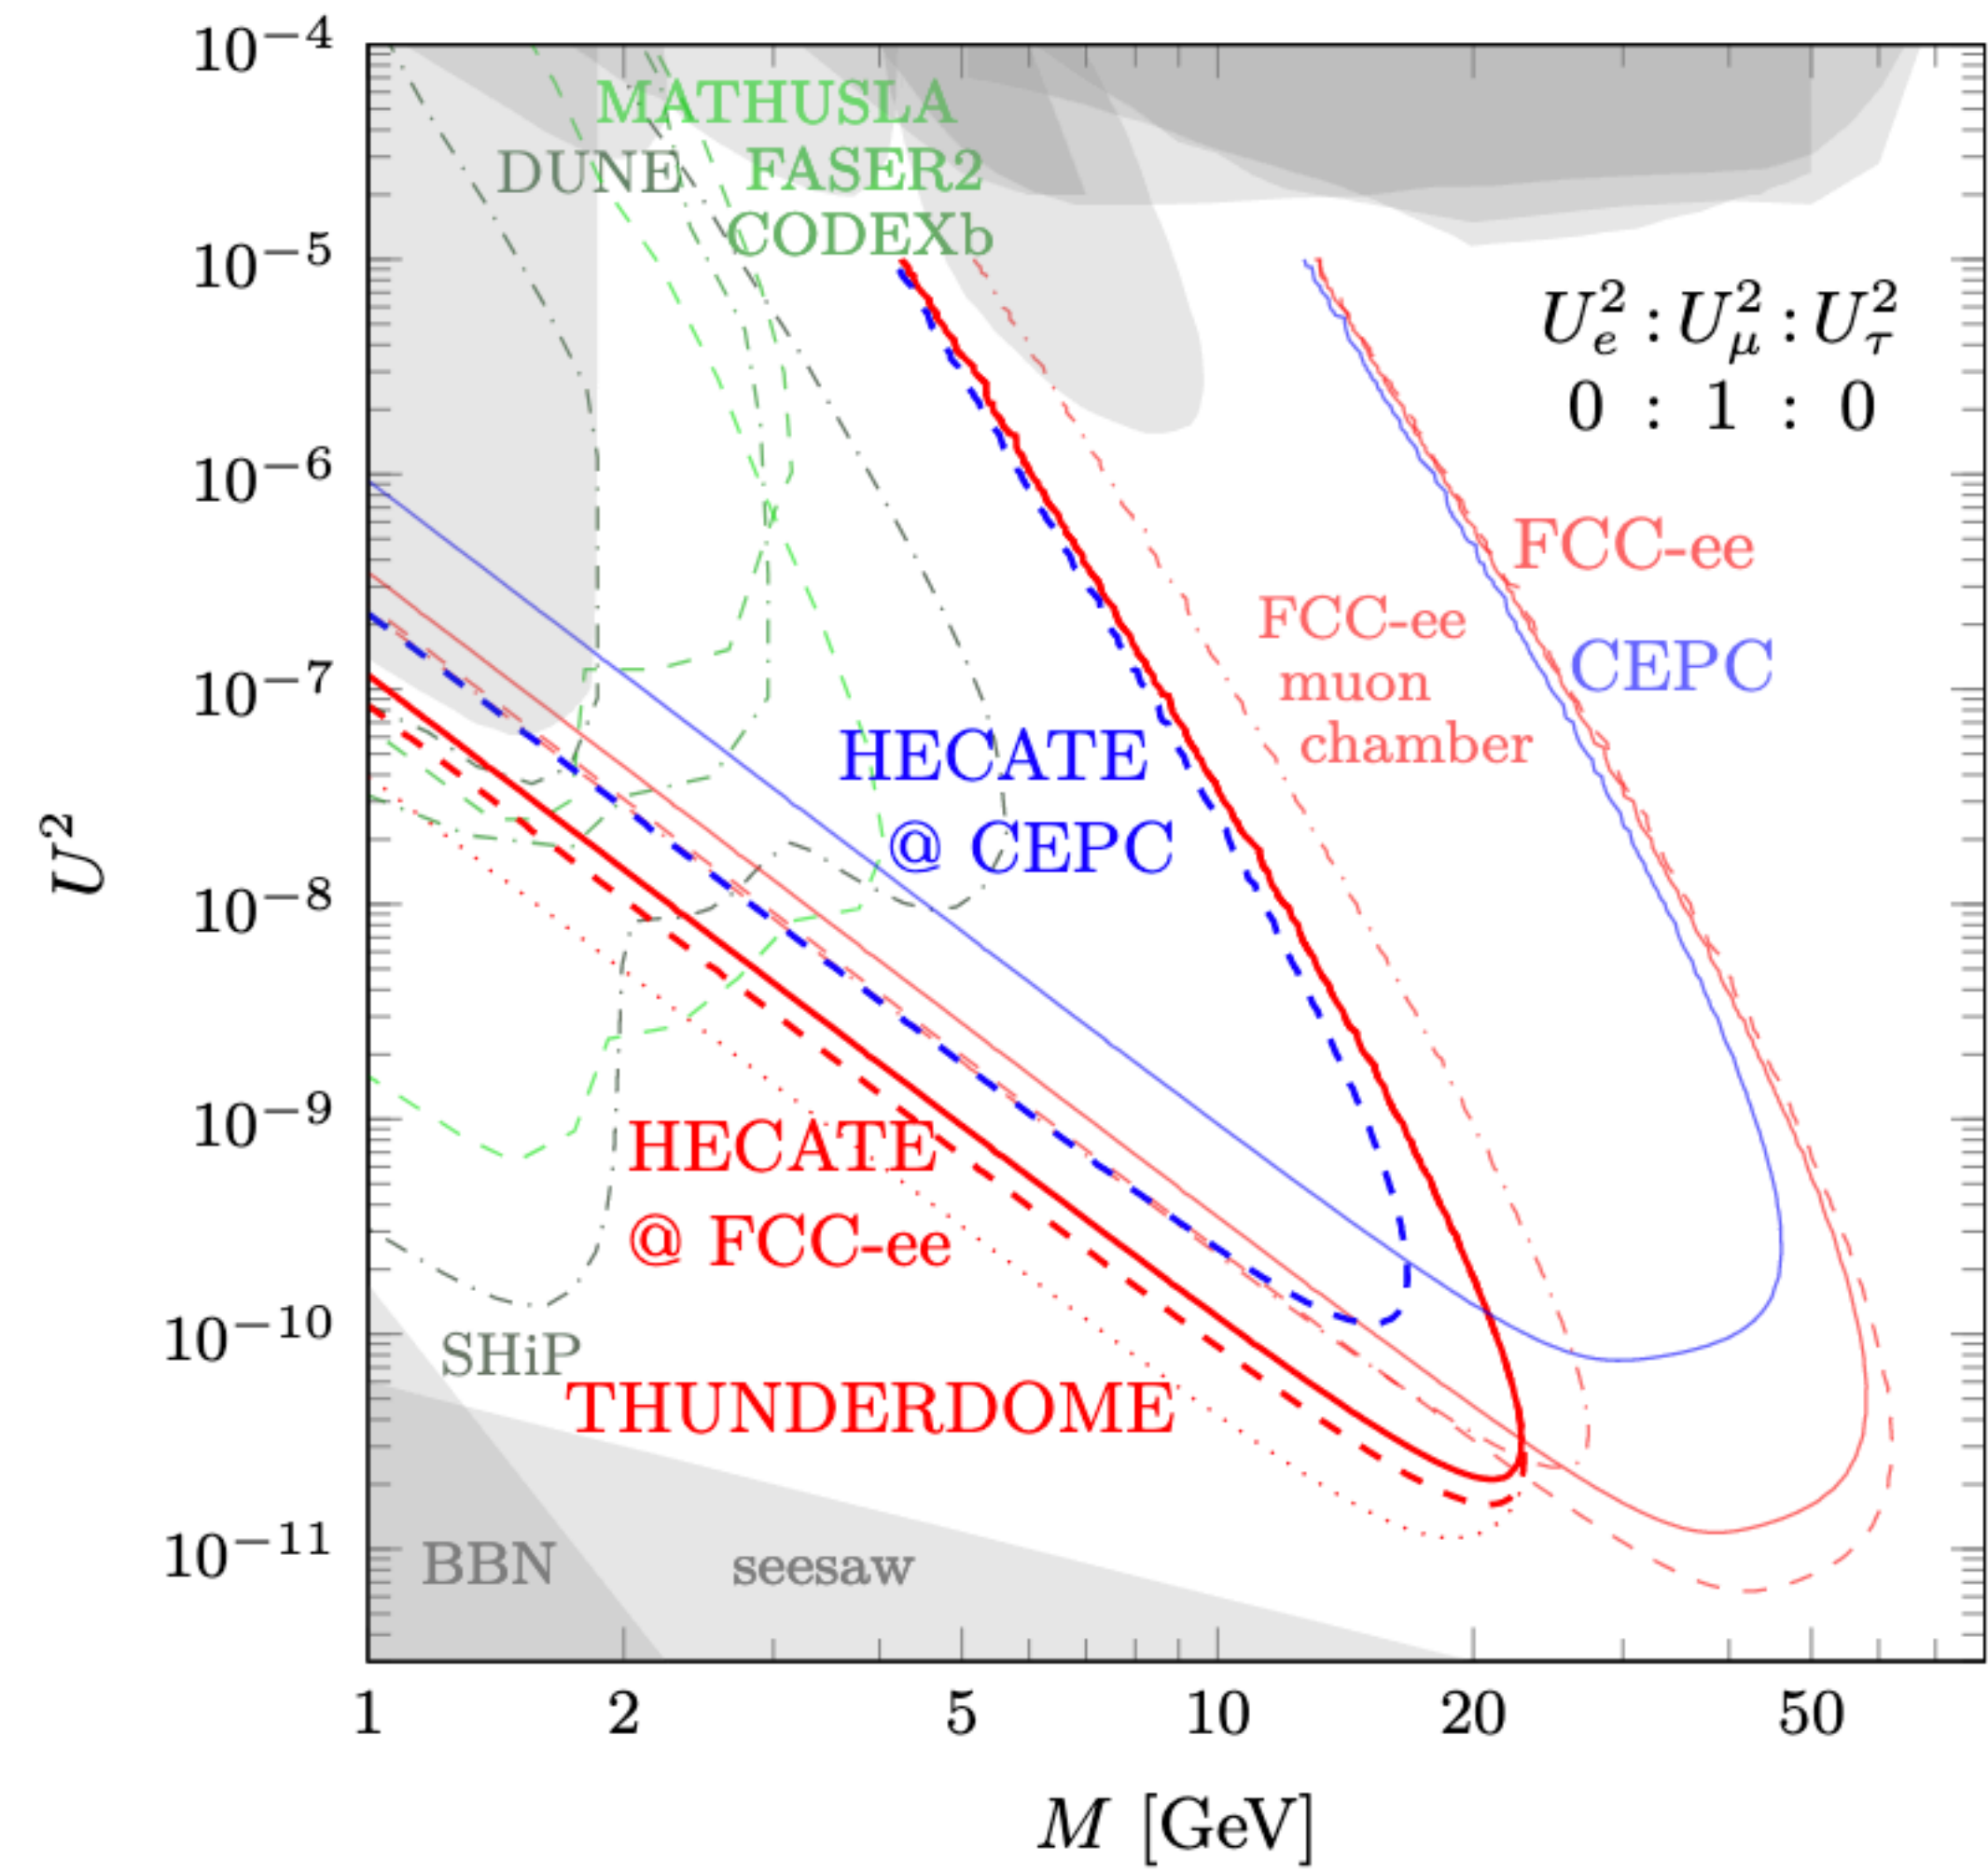

Ryu Sawada

# A dream LLP detector?

Time to incorporate LLP to the design of the future collider Experiments!

Including additional  
experiments!  
e.g. FCC-ee/CepC Mathusla-  
like concept HECATE:  
[arXiv:2011.01005](https://arxiv.org/abs/2011.01005)

# FINAL Quiz!

# What do you think of long-lived particles now?

# Summary

- LLP searches are a very attractive alternative (and complement) to mainstream new physics searches at colliders
- **There are many interesting lines to explore connected to long-lived particles**
  - **Very much relevant to dark matter and hidden sector searches**
    - Heavy Neutral Leptons, Hidden sectors, exotic Higgs decays...
- **Experimentally, these searches are extremely challenging and fun**
  - But challenge conventional reconstruction and trigger methods
  - An opportunity to think **out-of-the-box**
- We are currently deciding on the next particle collider after the LHC
  - The HL-LHC upgrade of the LHC already will provide new opportunities
- LLP studies then and beyond will still require custom detector design, reconstruction algorithms, triggers

# Discussion session today

**17:30 (Lund time)**

- Join Monica and I together with a group of invited experts for a discussion on a few specific analyses
- Have your questions ready!

17:15 → 17:30 Discussion

▼ K308 Teorilabbet 

17:30 → 18:15 Extended discussion & tutorials: Collider searches for Dark Matter; led by Monica D'Onofrio and Rebeca Gonzalez Suarez

📍 K308 Teorila... 

18:15 → 19:30 Welcome reception

📍 K308 Teorilabbet
